2 CIRCUIT DESCRIPTION

2.1 General information

The 80-406 has three printed circuit boards. Circuitry is divided in the following sections:

- Microprocessor/Control
- VCO/Synthesizer
- Transmitter
- Receiver
- Signalling
- Battery

Refer to the Block Diagram and the Schematics.

2.2 Microprocessor/control

The microprocessor **Q17** is constantly operating when the radio is turned ON. It is continuously monitoring the keyboard, the PTT line and other internal inputs such as the squelch detect, etc. When a change occurs, the microprocessor makes the appropriate response. The microprocessor is used for control. The Radio emits a beep on channel change and the synthesizer is loaded with the correct frequency information. The microprocessor runs off a 8 MHz oscillator which is composed of **X1**, **C30**, **C31** and **R48**.

When the radio is first turned on, the microprocessor reads the radio status from the EEPROM Q8.

The microprocessor determines the receive frequency codes, then loads the synthesizer via its pins **42** (PLL LE), **46** (PLL CLK) and **43** (PLL DATA).

The microprocessor is fitted with an internal program flash memory as well, therefore functions can be customised, if necessary, upon specific request from the customer (fees may apply).

2.3 VCO / Synthesizer (PLL)

This section consists of the Temperature-Compensated Crystal Oscillator (TCXO), Voltage Controlled Oscillator (VCO), Synthesizer and the Loop Filter.

2.3.a Temperature-Compensated Crystal Oscillator (TCXO)

The reference oscillator ($\dot{X}401$) is a temperature compensated crystal- oscillator, **RV402** is used to adjust the oscillator on frequency (14.4 MHz) at room temperature (22 $\,$ \dot{Z}). The reference oscillator is held within the specified ± 2.5 PPM from -30 to $\pm 60^{\circ}$ C.

2.3.b Voltage-Controlled Oscillators

Only one of the VCOs runs at a time, which is controlled by **Q420** and **Q17**. When the PTT is pressed, **Q17** pin **34** goes low (approx. 0V) disabling the receive VCO by the **Q420** and biases on **Q419** to enable the transmitter VCO.

The receive VCO consists of **C989-C994**, **CV901**, **L926-L428**, **L933**, and **Q922-Q923**. This VCO oscillates at 45.1 MHz below the programmed receive frequency. The VCO's oscillating frequency is tuned by the varactor **Q923**. The tuning voltage is supplied from the output of the Loop Filter. The output of the VCO is AC coupled to the output buffer **Q914**. The buffered output is coupled to the synthesizer by **R558**, **C530**, and **C505**.

The transmitter VCO consists of C980-C985, C987, CV901, L924, L925, L929 and Q916, Q917.

This VCO oscillates on the programmed transmit frequency. The VCO's oscillating frequency is tuned by the varactor **Q417**. The tuning voltage is supplied from the output of the Loop Filter. The output of the VCO is AC coupled (**C979**) to the output buffer **Q915**.

The transmit voltage controlled oscillator is directly frequency-modulated and operates on the carrier frequency. In the receive mode, the transmit VCO is disabled and the receive VCO is enabled, producing the receive local oscillator signal at a frequency 45.1 MHz below the incoming receive frequency.

The synthesizer is tuned in 5.00 KHz or 6.25 KHz step.

2.3.c Synthesizer

The frequency synthesizer is a large scale monolithic synthesizer integrated circuit Q429.

The synthesizer IC contains a dual modular prescaler, programmable divide-by-N counter, prescaler control (swallow) counter, reference oscillator, reference divider, phase detector, charge pump and lock detector.

Also, included in Q429 are shift registers and control circuits for frequency controls and general device control.

RF output from the active VCO is AC coupled to the synthesizer **Q429** prescaler input at Pin **8**. The divide-by-N counter chain in **Q429**, consisting of the dual-modulus prescaler, swallow counter and programmable counter, divides the VCO signal down to a frequency very close to 5.00 KHz or 6.25 KHz which is applied to the phase detector. The phase comparator compares the edges of this of this signal with that of the 5.00 KHz or 6.25 KHz reference signal from the reference divider and drives the external charge pump (**Q425** and **Q426**).

The synthesizer unlock detector circuit prevents the operation of the transmitter, when the phase lock loop (PLL) is unlocked. The following discussion assumes the unit has been placed in the transmit mode. Q429 lock detector Pin 7 goes high when the PLL is locked. This high level is applied to Pin 21 of the microprocessor Q17. A software timing routing brings the RX/TX line low (Pin 29 of Q17), feeding this signal through the switch/buffer Q15. With the RX/TX line low, Q223A is cut off and Q223B is biases on passing +5VTX to Q431B, it biases on Q430 to pass switched TX B+ to the transmitter amplifier string which enables transmission.

When the PLL become unlocked, the lock detector at **Q429** Pin7 will begin pulsing low. A RC circuit converts pulsing low to a low level for the microprocessor. The microprocessor then changes the RX/TX line to a high, thus signalling the other transistor switches to drive **Q430** into cutoff which disable transmission. Therefore, the transmitter remains disabled while the loop remains out of lock.

2.3.d Loop Filter

The Loop Filter, a passive lead-lag filter consisting of **R461-R464** and **C493-C495**, integrates the charge pump output to produce the DC turning voltage for the VCO. One parasitic pole, consisting of **R461/C493** and RF chokes **L428/L429**, prevent modulation of the VCOs by the 5.00 KHz or 6.25 KHz reference energy remaining at the output of the loop filter. Direct FM is obtained for modulating frequencies outside the PLL bandwidth by applying the CTCSS/DCS signals and the pre-emphasized, limited microphone audio to the VCO modulation circuit.

The modulation circuit consists of R452, Q421 and C487.

2.4 Transmitter

2.4.a RF Power Amplifier

After the PTT is pressed, the +5VTX line switches to approximately 5V. Q919 is turned on enabling transmit VCO.

The VCO buffer, pre-driver, driver and power amplifier are biased on by **Q430**, which is biased on by the **+5VTX** line switching to 5V. RF output from the transmit VCO(**Q916**) is applied to the VCO output buffer **Q915**.

Output from Q915 feeds the pre-driver amplifier Q413. The output signal from Q413 feeds the driver amplifier Q412, whose output from the driver stage feeds the final RF power amplifier Q407 to produce the rated output power of 5 watts. The output of the final is applied to a low-pass filter(C451, C452 and L413) and then to the transmit/receive switch Q402. RF power is then fed to the antenna via the output low-pass filter consisting of C401,C403, C405-C408, L401, and L402.

2.4.b Antenna Switching

Switching of the antenna between the transmitter and the receiver is accomplished by the antenna transmit/receive switch consisting of diodes Q401 and Q402 in conjunction with C410 and R402. In the transmit mode, switched TX B+ is applied through R420 and RF choke L414,hard forward biasing the two diodes on. Q402 thus permits the flow of RF power from output of the low-pass filter fed by the output amplifier to the output lowpass filter. Q401 shorts the receiver input to C410, which is AC coupled to ground. L403, C409, C410 and R402 then function as a lumped constant quarter-wave transmission line, thus presenting a high impedance to the RF output path, effectively isolating the receiver input and transmitter output sections.

2.4.c Power control

Output power is controlled via the dual Op-Amp (Q408), which is used as a differential amplifier and comparator.

Current is sensed by the voltage drop across **R421** and **R422**. This voltage is compared to the one set by the 5 watt Adjustment **RV401**. The power output is then reduced or increased by varying the **Q410**'s output voltage applied to the power amplifier **Q407**'s pin 2.

2.4.d Transmitter Audio Circuits

The transmitter audio circuits consist of the audio processing circuits, the CTCSS circuits and the DCS circuits.

2.4.e Audio Processing

Transmit speed audio is providing by either the internal electric microphone M101 or the external microphone. The microphone audio is applied to MIC MUTE SW Q235, and Lo-pass filter Q214A, Q214B. The audio is pre-emphasized by 6dB per octave by C236 and R284, and then signal amplification.

Limiting the peak-to-peak output. Under these conditions, the MOD. ADJ. Pot **RV201** configured as a four-pole active low-pass filter. The resulting signal is then limited when respect to side band splatter, and has an 18 dB per octave roll-off above 3 KHz.

The audio is then applied to transmit VCO. By varying the voltage on the varactor diode **Q421** at an audio rate. The resonant frequency of VCO is varied. The result is an oscillator output that is frequency -modulated at the audio frequency.

2.5 Receiver

2.5.a Receiver Front End

In the receive mode, the RF signal enters thorough the antenna, then through the low-pass filter C404, C405, C407 - C409 and L401-L403. The diodes Q401 and Q402 are biased off so that the output of the low-pass filter is coupled (C411) to the first band-pass filter C811-C818, C822-C823, L801-L803. The signal from the band-pass filter is applied to the input of the RF amplifier Q804.

The output of the RF amplifier feeds the input to three more stages of band-pass filters consisting of **C825-C839**, and **L804-L808**. The output from the band-pass filter is applied to the mixer's **Q405/L411**.

2.5.b Local Oscillator (LO)

The Receive VCO (C989-C994, CV901, L926-L927, L933, Q922-Q923 and R953) provides the LO signal. The VCO is running at 45.1 MHz below the desired receive frequency and is applied to output Buffer Q915/Q414. The output of the buffer through the low-pass filter C433-C435, L432-L433 and applied to the mixer Q405/L411/L412.

2.5.c Mixer

The mixer is a DBM type (L411,Q405,L412). The mixer LO frequency is 45.1 MHz below the desired receiver frequency.

When the receiver frequency is present, the mixer output will be a 45.1MHz signal. The mixer output is peaked for 45.1MHz at **L434**, **C437** and **R413**, and the signal is filtered by crystal filter **F401A** and **F401B** and amplified by **Q406** before being applied to the input of the IF IC **IC6**.

Inside IC6, the 45.1MHz IF signal becomes the input to a second mixer with a LO frequency of 44.645 MHz set by X201. The 455 KHz ceramic filter F201 or F202 filters the second mixer's output which is the second IF signal. The mixer's output is then fed to the internal limiting amplifier and then on to the FM decoder.

2.5.d FM Detector and Squelch

The FM detector output is used for squelch, decoding tones and audio output. The setting of the squelch adjustment potentiometer **RV205** sets the input to the squelch amplifier.

The squelch amplifier is internal to IC6 and its output is fed to an internal rectifier and squelch detector.

The output on IC6 Pin 14 signals the microprocessor Q17 with a low level (~0V) to unmute the radio.

The audio is unmuted by the microprocessor **Q17** Pin 27 switching to a high value (~5V on SQL MUTE) thus biasing on **Q206**. The audio is then routed to the audio amplifier **Q221** via the volume control **S201**.

2.5.e Receiver Audio Circuit

The detector's audio output also is fed to the tone(CTCSS and DCS) low-pass filter Q212C.

Then the output of the low-pass filter is routed to the second stage filter Q212B. The output of Q212B is applied to the squaring circuit Q212A and finally to the microprocessor Q17 Pin 60 for decoding.

Another branching of the detector output feeds the audio high-pass filter **Q208** via **Q212D**. The output of the audio high-pass filter feeds the Volume Control **S201**(VOL). From the wiper arm on the Volume Control, the audio is routed to Pin 2, the input to the audio power amplifier **Q221**. The output of the audio power amplifier is routed through the earphone jack **J401** to the internal speaker **E101**.

2.6 Signalling

2.6.a General

The microprocessor is fitted with a ADC/DAC converter built-in, so it provides generating and decoding the tones for selective calls, CTCSS and DCS. It can do that without using any other external ICs, but only by means of some transistors. The deviation of the selective call can be adjusted by the trimmer RV1.

The microprocessor manages the analogue switches for the scrambler as well, which is base-band-inversion type.

2.6.b CTCSS Tone Encoder / Digital Code Squelch (DCS) Encoder

CTCSS signals and DCS signals are synthesized by microprocessor **Q17** and appear as pulse waveform on I/O line at Pin **39**. This I/O line is a pseudo-sine wave for CTCSS or a DCS pseudo-waveform and is applied to the transistor **Q5** which makes the signals closer to the theoretic CTCSS/DCS signals. The waveform is then smoothed by low pass filters **Q213B** to produce an acceptable sine wave output. The CTCSS tone signal is adjust to the proper level by **RV202**. The DCS signal is adjust to the proper balance by **RV203**. The signal is then applied to the audio processing circuit at **R305** and to the TCXO circuit at **X401**.

2.6.c Selective call

Similarly to CTCSS/DCS, selcal signals are also generated and decoded by the microprocessor Q17. The selcal decode input is the pin 59 (ADC_SELCALL), whilst the TX tones are generated at pin 37 (SELCALL_PWM), then fed to the transistor Q4 and associated circuitry which provides to amplify and smooth the tones in order to make them suitable for the modulator. RV1 adjusts the level (deviation) of the tones.

2.6.d Scrambler

It's a classic "baseband inversion" scrambler which inverts the audio baseband (300-30000 Hz). The audio baseband AFTX_IN is mixed with a fixed tone (1300 Hz) SCRMBLR_CLK generated by the microprocessor Q17. The mixer's output AFTX_OUT is a scrambled baseband which sounds garbled (not understandable) by normal receivers. However, if the receiver is equipped with the same kind of scrambler which is properly set on the same fixed tone, the received scrambled baseband is fed in the RX mixer which provides a complementary process obtaining a clear (understandable) baseband at its output. If fact if the scrambled transmission is received by the party's 80-106 (with scrambled activated), the scrambled baseband AFRX is fed to the scrambler unit and mixed with the same tone generated by the microprocessor. The output of the mixer AFRX_OUT is a normal (unscrambled) baseband and can be clearly heard.

As you can see, the over stated fixed audio tone acts as a encoding/decoding key, so it must be the same both at the TX and RX parties. As already stated, the standard version of 80-106 is fitted with a 1300 Hz encoding/decoding key, however a different tone can be required.

2.7 Battery

The battery connects to the contact pins(CN201 and CN202) on the bottom end of the Radio. The positive terminal of the battery connects to the ON/OFF Volume Control switch (S201) and the negative terminal connects

to chassis ground. Low battery sense R101/R102, voltage regulator Q222 and transmit power module Q407.

80-106 Service Manual

The battery voltage status is monitored by the microprocessor Q17 Pin 61 which senses the battery voltage through the BATT+SW line by means of R51/R49. When the battery voltage is approximately 5.8V, the microprocessor considers the battery discharged and switches off the circuits of the radio.

When the Radio is on a channel with no tone programmed, the BATTERY SAVER Mode is enabled when programmed.

In the BATTERY SAVER mode, the microprocessor **Q17** generates a square wave signal at Pin **48** which is applied to the inverter **Q10-F**. The signal's duty cycle varies according to what the POWER SAVE TIMER is set. When the microprocessor **Q17** Pin **48** goes high (approx. 5 V) **Q226** (receiver module) is biased off, **Q225** is biased on, **Q224A** is cut off, and **Q223A** is cut off, thus turning the supply off to **C6**.
