Transmitter Power(EIRP) Measurement (§24.232)

The measurement were performed shown as follows.

Step 1) The test was set-up shown as Fig.3(a). In order to obtain the maximum emission, the EUT is placed at the height 1.0m on the non-conducted support and the center of the Adaptive Array Antenna is set to 2.3m at the distance 3m from the receiving antenna(Horn Antenna) and rotated around 360 degrees. The receiving antenna height was varied from 1m to 4 m . Then the meter reading of the spectrum analyzer at the maximum emission was A dB(μ V).

The Details of Test-Arrangement on Radiated emission test (Drawings) is shown in page 34.

Step 2) The test was set-up shown as Fig.3(b). the center of the Adaptive Array Antenna was replaced to Horn antenna at the same polarized under the same condition as step 1. The RF power was fed to the transmitting Antenna(horn Antenna) through the RF amplifier from the signal generator. In order to obtain the maximum emission level, the height of the receiving antenna is varied from 1m to 4 m. The level of the signal generator was adjusted so that the meter reading of the spectrum analyzer at the maximum emission was A dB(μ V) ,same as the recorded level in Step1. Then the RF power into the substitution horn antenna was P(dBm).

The EIRP is calculated in the following equation.

$$\text{EIRP(dBm)} = P \text{ (dBm)} + G_h(\text{dBi})$$

Where, $G_h(\text{dBi})$: Gain of the substitution horn antenna

Fig.3 Maximum Transmitter Power (EIRP) Measurement

Unwanted Radiation Measurement (§2.1053,§24.238)

- ERP method -

Step 1) The spurious radiation for transmitter were measured at the distance 3m away from the EUT which was placed on a non-conducted support 1.0m in height and the center of the Adaptive Array Antenna was set to 2.3m. The receiving antenna was oriented for vertical polarization and varied from 1 m to 4 m until the maximum emission level was detected on the measuring instrument. The EUT was rotated 360 degrees until the maximum emission was received. The measurement was also repeated with the receiving antenna in the horizontal polarization.

The Details of Test-Arrangement on Radiated emission test (Drawings) is shown in page 34.

This test was carried out using the loop antenna for up to 30MHz, using the half-wave dipole antenna for up to 1GHz and using the horn antenna for above 1GHz.

Step 2) The EIRP measurement was carried out with according to Step 2 in page 7 . Then the RF power in the substitution antenna half-wave dipole antenna for up to 1GHz and the substitution horn antenna for above 1GHz.

The EIRP is calculated in the following equation.

A) Up to 1GHz

$$\text{EIRP(dBm)} = P \text{ (dBm)} + G_d(\text{dBi}) - (\text{Balun Loss of the half-wave dipole Ant. (dB)}) + \text{Cable Loss(dB)}$$

Where, $G_d(\text{dBi})$: Gain of the substitution half-dipole antenna

B) Above 1GHz

$$\text{EIRP(dBm)} = P \text{ (dBm)} + G_h(\text{dBi})$$

Where, $G_h(\text{dBi})$: Gain of the substitution horn antenna

The ERP is calculated in the following equation.

$$\text{ERP[dBm]} = \text{EIRP (dBm)} - G_d(\text{dBi})$$

The respective calculated EIRP of the spurious and harmonics were compared with the EIRP and ERP of fundamental frequency by specified attenuation limits, $43 + 10 \log_{10}(\text{TP in watt})[\text{dB}]$. Where, TP = Transmitter power at the ANT OUT under test configuration as the handsfree unit used.

The tests were carried out under one test configuration as the handsfree unit used.

AC Powerline Conducted Emission 150 kHz - 30 MHz:

The preliminary test was performed according to the description of ANSI C63.4-2001 Sec.7.2.3 (Exploratory AC Powerline Conducted Emission Measurements) and Sec.6.2.1 (Tabletop Equipment Tests).

The preliminary test was carried out to investigate the frequency of the emission that has the highest amplitude relative to the limits within normal operating modes, cable positions, and a typical system configuration. In order to find out to the maximum emission, the preliminary test and a final test were performed in accordance with the following steps.

Step 1: One operation mode of the test system was setting.

Step 2: Using both of a spectrum analyzer and a test receiver, the emission's circumstance from the system was monitored in one of ten divided frequency bands of the specified frequency range (150 kHz - 30 MHz). The maximum emission in the band was found by changing the typical cable positions or cable manipulation under a typical system configuration and by selecting of current-carrying conductor. The level and the frequency at the one point which are regarded as relative high emission in the band was measured and recorded. This step was repeated until the ending frequency band.

Step 3: Return to step 1, if the other operation mode was possible to be setting.

Step 4: Based on the collected results, the operation mode produced the maximum emission was selected. The final test on the selected operation mode was performed. But if it was difficult to select the operation mode, the final tests on all operation modes were performed.

Step 5: Based on the same data, as result if the final measurement, at the worst point that has the highest amplitude relative to the limit the repeatability of the worst was reconfirmed.

The photographs of the test system setup on the worst point were taken and recorded.

Sample of calculated result at 3819.1 MHz, as the Minimum Margin point:

$$\begin{array}{rcl} \text{Corr. Factor} & = & -19.4 \text{ dB} \\ +) \text{ Meter Reading} & = & -6.3 \text{ dB}(\mu\text{V}) \\ \hline \text{Result} & = & -25.7 \text{ dB}(\mu\text{V}) \end{array}$$

Minimum Margin: $-13.0 - (-25.7) = 12.7 \text{ (dB)}$

The point shown on “_____” is the Minimum Margin Point.

Applied Limits:

$$-13.0 \text{ [dBm]} = 10\log(\text{TP[mW]}) - (43 + 10\log(\text{tp[W]})) = 10\log(\text{TP[mW]}) - (43 + (10 \log(\text{TP[mW]}) - 30))$$

where $\text{tp[W]} = \text{TP[mW]} / 1000$: Transmitter power at antenna terminal

$$10\log(\text{tp[W]}) = 10\log(\text{TP[mW]}) - 30$$

Correction factor details:

Cable Loss + 10dB Pad Att. [dB] (9 kHz - 2.2 GHz)

Cable Loss + 20dB Pad Att. + High Pass Filter Loss (D-42) - Pre-Amp. Gain [dB] (over 5.8 GHz)

- Note: 1) The spectrum was scanned 9 kHz to 20 GHz and all emissions not reported were more than 20 dB below the applied limits.
2) The spectrum analyzer displays were printed out in Attachment B.

Remarks:

Maximum Permissible Exposure(MPE) :

The limit for Maximum Permissible Exposure(MPE) at frequency of 1894.85 MHz is 1.00 mW/cm². (1.00 mW/cm² for General Population/Uncotrolled enviroment in §1.1310.)

The conversion from power to power density uses the following equation :

$$PD = (TPG)/4\pi r^2 = EIRP/4\pi r^2$$
$$r = \text{SQRT}(EIRP/4\pi PD)$$

Where : PD : Power Density at the Minimum Save-distance(W/m²)

TP : Transmitt Power (W)

G : Numeric gain of the antenna

EIRP: Equivalent Isotropically Radiated Power

r : Minimum Save-distance(in m)

The conversion from mW/cm² to W/m² is: 1mW/cm² = 10W/m²

Maximum EIRP*¹ : 154.88W

Note) *¹ : Measured Value

Minimum Save-distance for MPE calculation

Items	Value

PD (mW/cm ²)	1.00
PD (W/m ²)	10.00

Sample of calculated result at 2.44 MHz, as the Minimum Margin point:

$$\begin{aligned}
 &\text{Corr. Factor} = 0.2 \text{ dB} \\
 &+) \text{ Meter Reading} = 33.0 \text{ dB}(\mu\text{V}) \\
 &\hline
 &\text{Result} = 33.2 \text{ dB}(\mu\text{V})
 \end{aligned}$$

Minimum Margin: 56.0 - 33.2 = 22.8 (dB)

The point shown on “ ” is the Minimum Margin Point.

Note: The correction factor includes the AMN insertion loss and the cable loss.
