

MPE Prediction for Andrew INCELL800 Repeater

Maximum peak power output at antenna input terminal: +22 dBm (158.5 mW)

Maximum antenna gain: 7 dBi (5 numeric)

Prediction distance: 20 cm

MPE limit for uncontrolled exposure at tx frequency of 869 MHz: $869/1500 = .579 \text{ mW/cm}^2$

Using the equation from page 18 of OET Bulletin 65, Edition 97-01 to predict the worst-case exposure at 20 cm:

$$S = \frac{PG}{4\pi R^2}$$

where: S = power density

P = power input to the antenna

G = power gain of the antenna in the direction of interest relative to an isotropic radiator

R = distance to the center of radiation of the antenna

$$S = \frac{158.5 \times 5}{12.6 \times 400} = .157 \text{ mW/cm}^2$$

The normal worst-case arrangement of the antenna would be mounted in a ceiling tile. This would guarantee that the antenna would never be closer than 20 cm to any person.

To actually exceed the limit of $.579 \text{ mW/cm}^2$, the antenna unit would need to be closer than 10.4 cm. to any person.

The maximum allowable gain with a 20 cm. separation would be:

$$G = \frac{S \times (4\pi R^2)}{158.5} = \frac{.579 \times (12.6 \times 400)}{158.5} = 18.4 (\text{numeric})$$

$$10\log(18.4) = 12.7 \text{ dBi}$$

Given the above information, the manufacturer recommends a minimum separation distance of 20 cm. and maximum antenna gain of 12.7 dBi.
