## 3 Test Summary

### 3.1 Measurement Environment

This measurement experiment adopted an antenna near-field measurement system, and the diagram of the measurement system was shown in Figure 3-1. The excitation signal was generated by the Keysight E5071C (300kHz-20GHz). Under the control of the central computer, the probe rotated in the  $\theta$  direction, and the EUT rotated in the  $\phi$  direction with the turntable. The probe sampling frame received and collected signals in the near-field range of the EUT. The software system which was controlled by the central computer completed the processing, output and display of the test data.

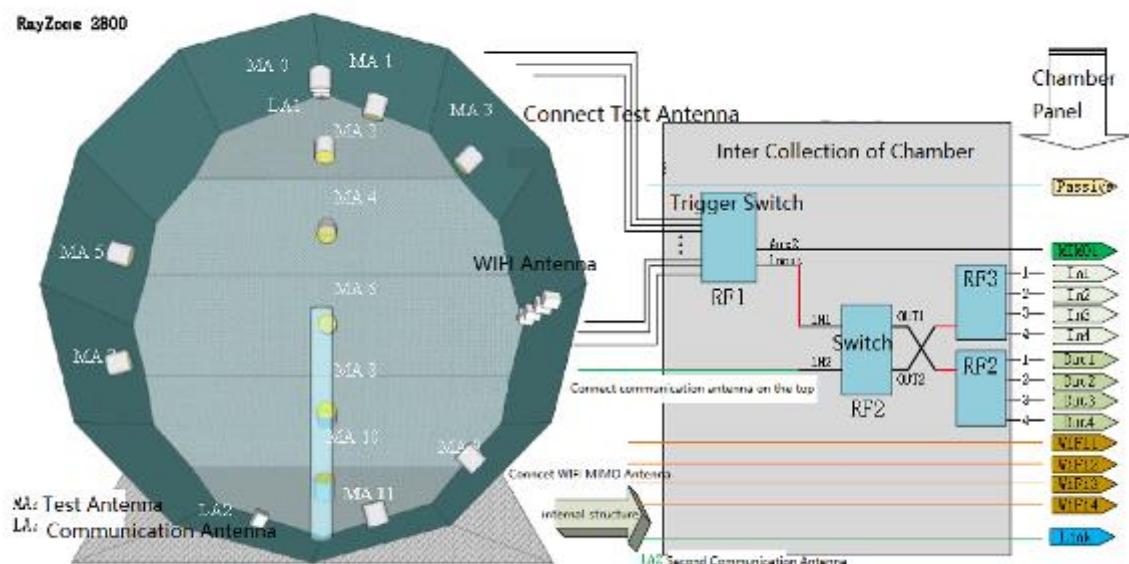

Figure 3-1 Schematic diagram of antenna near-field measurement system

The test site was a full anechoic chamber with a size of  $3.0m \times 3.1m \times 2.97m$ , which was built by GTS Rayzone2800. All six surfaces of the anechoic chamber were pasted with absorbing materials. And the chamber was calibrated by the authoritative third-party lab every year. The antenna anechoic chamber measurement system adopted a 13-probe multi-probe system. The probe antennas were evenly distributed on the spherical surface surrounding the EUT, and their operating frequency was 600MHz~8.5GHz.

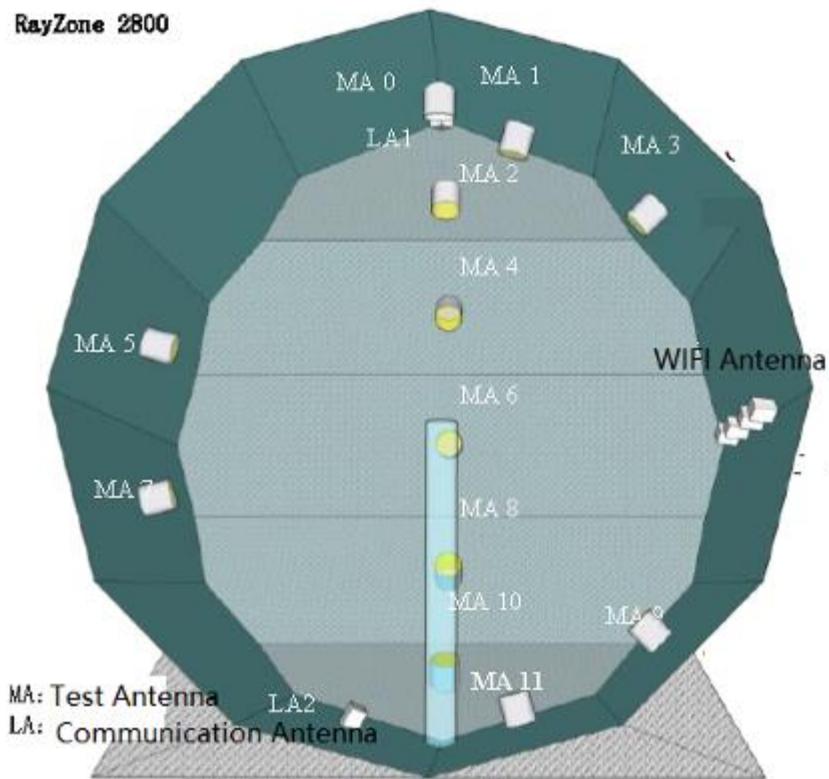

Figure 3-2 Antenna anechoic chamber for near-field measurement

During the measurement, the probe antennas were rotated in the  $\theta$  direction under the control of the probe holder to sample the near-field data at the  $\theta$  angle. At the same time, the EUT rotated with the turntable in the  $\varphi$  direction to sample the near field data at the  $\varphi$  angle. The system diagram was shown in Figure 3-3. From the sampling results, the EUT's near-field test data of  $\theta$  component,  $\varphi$  component and total component could be obtained.

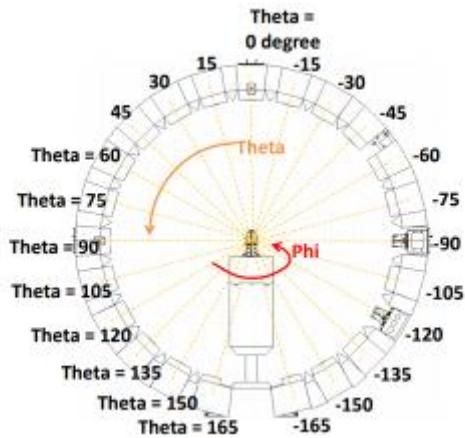

Figure 3-3 System diagram

Before the measurement, calibrated the vector network analyzer, and then connected the input end of each antenna to the output end of the vector network analyzer, and evenly the antennas to be measured. The Calibration information was shown in table 3-1.

## 3.2 Measurement Quantity

In this measurement experiment, the Directional Gain was measured at a certain frequency interval within the whole frequency range. The measurement frequency interval of the 2.4G antennas was 10MHz, while the 5G and 6G antennas was 50MHz,

## 3.3 Test Method

During the measurement, the probe antennas were rotated in the  $\theta$  direction under the control of the probe holder to sample the near-field data at the  $\theta$  angle. At the same time, the EUT rotated with the turntable in the  $\varphi$  direction to sample the near field data at the  $\varphi$  angle. The sampling accuracy was  $15^\circ$ . The system diagram was shown in Figure 3-5. From the sampling results, the EUT's near-field test data of  $\theta$  component,  $\varphi$  component and total component could be obtained.

### 3.4 Directional Gain Calculations

Multiple antennas system, each of which has one of two (or three) polarizations that are orthogonal to one another (i.e., cross polarized), The total gain—including array gain—is computed separately for each of the two (or three) polarizations using the procedures presented in this document. The highest of the total gains shall apply.

Theoretical Directional Gain represented the theoretical value calculated by formula 3-1. As we all know, the effect of array gain must be included in the calculation of overall directional antenna gain for devices that transmit on multiple outputs simultaneously in the same band, in the same or in overlapping frequency ranges. Therefore, in formula 3-1, the directional gain calculation needs to include all directions and all Frequencies and all Polarizations, and then take the maximum value as the final directional gain value. Therefore, the calculation formula of theoretical directional gain value can be modified as formula 3-2

$$\text{Directional Gain} = 10 \log \left[ \frac{\sum_{j=1}^{N_{\text{SS}}} \left( \sum_{k=1}^{N_{\text{ANT}}} g_{j,k} \right)^2}{N_{\text{ANT}}} \right] \quad (3-1)$$

Where

$N_{\text{SS}}$  = the number of independent spatial streams of data;  $N_{\text{SS}} = 1$ .

$N_{\text{ANT}}$  = the total number of antennas:  $N_{\text{ANT}} = 4$  for 2.4G & 5G & 6G antennas

$g_{j,k} = 10^{\frac{G_k}{20}}$  if the  $k$ th antenna is being fed by spatial stream  $j$ , or zero if it is not;

$G_k$  is the gain in dBi of the  $k$ th antenna .

$$\text{Directional Gain} = \text{Maximum} \left[ 10 \log \left[ \frac{\sum_{j=1}^{N_{\text{SS}}} \left( \sum_{k=1}^{N_{\text{ANT}}} g_{j,k} \right)^2}{N_{\text{ANT}}} \right] \right] \quad (3-2)$$

**Maximum** function is the max directional gain overall directions and all frequency all polarizations.

### 3.5 Test Procedure

The calculation method of DG (Directional Gain) in this scheme is summarized as follows:

- 1) The antenna anechoic chamber is used to measure the gain of each antenna, the gain of each antenna at this angle is taken every  $15^\circ$  to calculate the Directional Gain;
- 2) Use formula below to calculate and the Directional Gain of the system at this angle is obtained

$$\text{Directional Gain} = 10 \log \left[ \frac{\sum_{j=1}^{N_{\text{RF}}} \left( \sum_{k=1}^{N_{\text{ANT}}} g_{j,k} \right)^2}{N_{\text{ANT}}} \right] \quad (3-3)$$

- 3) For each frequency point, the Directional Gain value under 24 different angles can be obtained, and finally the maximum value is taken as the system Directional Gain value.
