## 2. Test setups

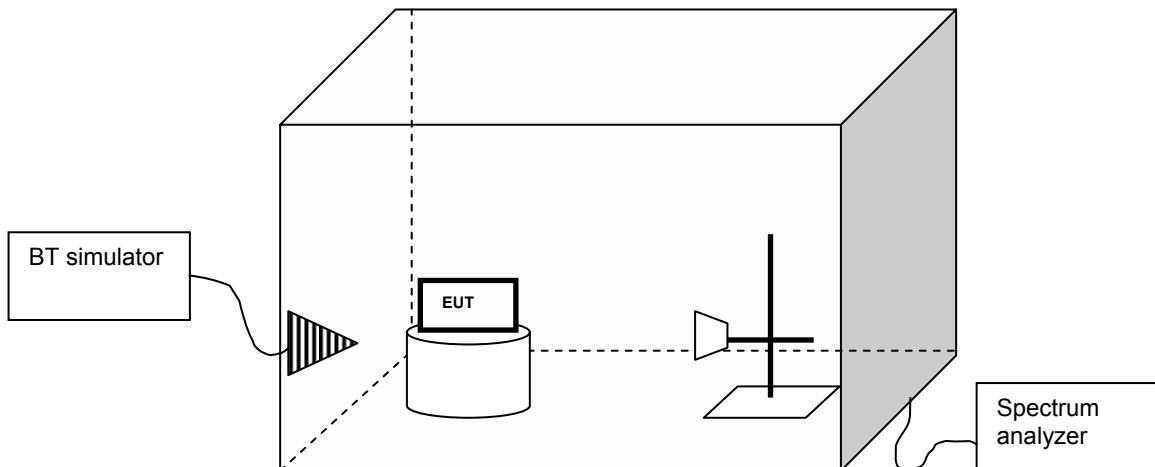

### Setup 1 (Conducted measurements)

The test was performed inside a shielded room. The Bluetooth simulator was used to control the EUT channel, number of EUT TX slots, enable/disable frequency hopping and modulate the TX signal with different bit patterns.

### Setup 2 (Radiated measurements)

The test was performed inside a semi anechoic shielded room. For the duration of the test the EUT was placed on a non-conductive support 0.8 m high standing on the turntable. In the corner of the chamber there was a communication antenna, which was connected to the BT simulator located outside the room. The radiated power from the EUT was measured with an antenna fixed to a antenna tower. The tower and turn table were remotely controlled to turn the EUT and change the antenna polarization. The measured signal was routed from the measuring antenna to the spectrum analyzer. The BT simulator was used to set the TX channel and modulate the TX signal with different bit patterns.

### 3. Standards and measurement methods

The test were performed in guidance of the CFR 47 part 15.247, part 2, FCC public notice DA 00-705 (March 30, 2000, ANSI C63.4 (1992) and RSS-210 (Issue 5, November 2001) and CISPR-22.

<i>EUT channel</i>	<b>0, 38 and 78</b>
<i>EUT TX power level</i>	<b>Nominal</b>
<i>EUT operation voltage</i>	<b>115 V / 60 Hz</b>

#### 4.8.2 Test method and limit

The test was performed in a semi-anechoic shielded room. The EUT was placed on a non-conductive 0.8 m high table standing on the turntable (photograph 1). During the test in the frequency range 30-2000 MHz the distance from the EUT to the measuring antenna was 3 m. During the test in the frequency range 2000-18000 MHz the distance from the EUT to the measuring antenna was 1.5 m. During the test in the frequency range 18-25GHz the distance from the EUT to the measuring antenna was 1 m. The excess length of the cables of the EUT were made into bundles 30-40 cm in length. In order to find the maximum levels of the disturbance radiation the angle of the turntable, the height of the measuring antenna and the lay-out of the EUT cables were varied during the tests. The test was performed with the measuring antenna being both in horizontal and vertical polarizations.

Vertical and horizontal polarizations in the frequency range 30 – 1000 MHz was measured by using the peak detector. During the peak detector scan the turntable was rotated from 0° to 360° with 30° step with the antenna heights 1.0 m and 3.0 m. The highest levels of the radiated interference field strength measured by using the quasi-peak detector were recorded.

Vertical and horizontal polarizations in the frequency range 1000 – 25000 MHz was measured by using the peak detector. During the measurement the turntable was rotated from 0° to 360° and the antenna was raised from 1.0 m and 4.0 m.

The CFR 47 Part 15, Subpart B, Class B limit of 500  $\mu\text{V}/\text{m}$  has been calculated to correspond 54 dB( $\mu\text{V}/\text{m}$ ) as follows: [dB( $\mu\text{V}/\text{m}$ )]=20log[ $\mu\text{V}/\text{m}$ ].

EN 55022 Class B limit (3m measuring distance)

Frequency band MHz	Quasi-peak limit dB( $\mu\text{V}/\text{m}$ )

#### 4.8.3 Test results

The measurement results were obtained as described below.

##### 4.9.1 Test method and limit

The test was performed inside a shielded room where the floor and one of the walls of the test site comprised the reference ground plane (RGP). For the duration of the test the EUT was placed on a non-conductive table 0.8 m high standing on the reference ground plane (see photograph 2). The excess length of the cables of the EUT were made into bundles 30-40 cm in length. The power input cable of the EUT was connected to an artificial mains network. The test was performed separately on the phase and also on the neutral wire.

The disturbances were first examined by performing a spectrum scan by using a peak detector. The general procedure in the conducted disturbance emission test is that no further measurements are necessary if the disturbance levels measured by using the peak detector are below the limit value defined for the measurement performed by using an average detector.

If not, then at the test frequencies concerned the measurement is performed also by using a quasi-peak detector. If the disturbance levels measured by using the quasi-peak detector are below the limit value defined for the measurement performed by using an average detector, then measurements by using the average detector are not necessary.
