Summary

Tests for compliance with FCC Regulations subject to Part 15, Subpart B, were performed on United Technologies Automotive WQW SEC Receiver. This device is subject to the Rules and Regulations as a Receiver. As a Digital Device it is exempt, but such measurements were made to assess receiver's overall emissions.

In testing performed on January 21 and 22, 1999, the device tested in the worst case met the allowed specifications for radiated emissions from the receiver section by 13.7 dB (see p. 6), and the antenna conducted emissions by 9.5 dB. The conductive emission tests do not apply, since the device is powered from an automotive 12 VDC electric system.

1. Introduction

United Technologies WQW receiver was tested for compliance with FCC Regulations, Part 15, adopted under Docket 87-389, April 18, 1989. The tests were performed at the University of Michigan Radiation Laboratory Willow Run Test Range following the procedures described in ANSI C63.4-1992 "Methods of Measurement of Radio-Noise Emissions from Low-Voltage Electrical and Electronic Equipment in the Range of 9 kHz to 40 GHz". The attenuation characteristics of the Open Site facility are on file with FCC Laboratory, Columbia, Maryland. (FCC file 31040/SIT)

2. Test Procedure and Equipment Used

The test equipment commonly used in our facility is listed in Table 2.1 below. The second column identifies the specific equipment used in these tests. The HP 8593E spectrum analyzer is used for primary amplitude and frequency reference.

Table 2.1. Test Equipment.

3. Configuration and Identification of Device Under Test

The DUT is a 315.0 MHz superegenerative receiver, designed for onboard automobile security/convenience applications and, as such, it is powered from an automobile 12 VDC source. The receiver is housed in a plastic case approximately 4.25 x 4.0 x 1.25 inches, plus a metal mounting bracket and one multi-pin connector for power input and digital signal output. For testing, a "generic" harness was made up, one bundle containing a pair of power-up wires and the other bundle containing (output) control signal wires. The length of the harness was about 2.0 m and the ends of signal wires were left open. In the receiver, decoding, signal processing, etc., are performed by a micro, timed by a 4.00 MHz oscillator.

The DUT was designed and manufactured by United Technologies Automotive, 5200 Auto Club Drive, Dearborn, MI 48126. It is identified as:

UTA SEC Receiver
Model: WQW
SN: FCCTEST
FCC ID: FOBUTAHZR
CANADA: 1983 102 156A

3.1 Modifications Made

There were no modifications made to the DUT by this laboratory.

4. Emission Limits

The DUT tested falls under Part 15, Subpart B, "Unintentional Radiators". The pertinent test frequencies, with corresponding emission limits, are given in Tables 4.1 and 4.2 below.

4.1 Radiated Emission Limits

Table 4.1. Radiated Emission Limits (Ref: 15.33, 15.35, 15.109).

Freq. (MHz)	E _{lim} (3m) μ V/m	E _{lim} dB(μ V/m)
30-88	100	40.0
88-216	150	43.5
216-960	200	46.0
960-2000	500	54.0

Note: Quasi-Peak readings apply to 1000 MHz (120 kHz BW)
Average readings apply above 1000 MHz (1 MHz BW)

4.2 Conducted Emission Limits

Table 4.2. Conducted Emission Limits (Ref: 15.107).

Freq. (MHz)	μ V	dB(μ V)
0.450 - 1.705	250	48.0
1.705 - 30.0	250	48.0

Note: Quasi-Peak readings apply here

The conductive emission limits do not apply here, since the DUT is powered from an automotive 12 VDC source.

4.3 Antenna Power Conduction Limits

Ref: 15.111(a). Pmax = 2 nW; for frequency range see Table 4.1.

5. Emission Tests and Results

NOTE: Even though the FCC and/or Industry Canada specify that both the radiated and conductive emissions be measured using the Quasi-Peak and/or average detection schemes, we normally use peak detection since especially the Quasi-Peak is cumbersome to use with our instrumentation. In case the measurement fails to meet the limits, or the measurement is near the limit, it is remeasured using appropriate detection. We note, that since the peak detected signal is always higher or equal to the Quasi-Peak or average detected signal, the margin of compliance may be better, but not worse, than indicated in this report. The type of detection used is indicated in the data table, Table 5.1.

5.1 Anechoic Chamber Radiated Emission Tests

To familiarize with the radiated emission behavior of the DUT, it was studied and measured in the shielded anechoic chamber. In the chamber there is a set-up similar to that of an outdoor 3-meter site, with turntable, antenna mast, and a ground plane. Instrumentation includes spectrum analyzers and other equipment as needed.

To study and test for radiated emissions, the DUT was powered by a laboratory power supply at 13.5 VDC. A 315 MHz CW signal was injected (radiated) from a nearby signal generator using a short wire antenna. The DUT was taped onto the test table on each of the three axis. At each orientation, the table was rotated to obtain maximum signal for vertical and horizontal emission polarizations. This sequence was repeated throughout the required frequency range.

In the chamber we studied and recorded all the emissions using a ridge-horn antenna, which covers 200 MHz to 5000 MHz, up to 2 GHz. In scanning from 30 MHz to 2.0 GHz, there were no spurious emissions observed other than the LO and injection signal (315 MHz), and the LO harmonics. Figures 5.1 and 5.2 show emissions measured 0-1000 MHz and 1000-2000 MHz, respectively. These measurements are made with a ridge-horn antenna at 3m, with spectrum analyzer in peak hold mode and the receiver rotated in all orientations. The measurements up to 1000 MHz (Fig. 5.1) are used for initial evaluation only, but those above 1000 MHz (Fig. 5.2) are used in final assessment for compliance.

5.2 Open Site Radiated Emission Tests

The DUT was then moved to the 3 meter Open Field Test Site where measurements were repeated up to 1000 MHz using a small bicone, or dipoles when the measurement is near the limit. The DUT was exercised as described in Sec. 5.1 above. The measurements were made with a spectrum analyzer using 120 kHz IF bandwidth and peak detection mode, and, when appropriate, using Quasi-Peak or average detection (see 5.0). Figure 5.3 shows the DUT on the test table; figure 5.4 shows the overview of the OATS with the DUT on the test table.

The emissions from digital circuitry were measured on the Open Site using a standard bicone. These results are also presented in Table 5.1.

5.3 Computations and Results for Radiated Emissions

To convert the dBm's measured on the spectrum analyzer to dB(μV/m), we use expression

$$E_3(\text{dB}\mu\text{V/m}) = 107 + P_R + K_A - K_G$$

where P_R = power recorded on spectrum analyzer, dB, measured at 3m
 K_A = antenna factor, dB/m
 K_G = pre-amplifier gain, including cable loss, dB

When presenting the data, at each frequency the highest measured emission under all of the possible orientations is given. Computations and results are given in Table 5.1. There we see that the DUT meets the limit by 13.7 dB.

5.4 Conducted Emission Tests

These tests do not apply, since the DUT is powered from an automotive 12 VDC source.

6. Other Measurements

6.1 Emission Spectrum Near Fundamental

Near operating frequency the emission spectrum is typically measured over 2 MHz span, with and without the injection signal. These data are taken with the DUT close to antenna and hence amplitudes are relative. The plots are given in Figure 6.1.

6.2 Effect of Supply Voltage Variation

The DUT has been designed to operate from 12 VDC power. Using a spectrum analyzer, relative conducted emissions were recorded at the "fundamental" (315 MHz) as voltage was varied from 5.0 to 18.0 VDC. Figure 6.2 shows the emission variation.

6.3 Operating Voltage and Current

$$\begin{aligned} V &= 13.8 \text{ VDC} \\ I &= 6.7 \text{ mADC} \end{aligned}$$

6.4 Antenna RF Power Conducted Measurements

These measurements are made by connecting a spectrum analyzer directly to the DUT antenna terminal and recording, in this case, the typical regenerative receiver "finger" pattern shown in Figure 6.3. Power readings of individual lines, plus other emissions if present, are summed up. In this case, the sum is 0.226 nW, which is 9.5 dB below the 2 nW limit. The peak line in Figure 6.3 is the locking signal and not counted as part of conducted emission. It injected into the receiver via radiation from a nearby antenna which, in turn, is connected to a signal generator.
