Alliance, Ohio 44601

MOTOR AND DRIVE CIRCUIT RADIATED EMISSIONS:

The radiated emissions data was gathered from the 3-meter range based on pre-scan data. The operator was activated and the emissions per 15-109 limits from the DC motor were measured at 3 meters (Table page 67).

RECEIVER RADIATED EMISSIONS:

The operator is delivered with a wire antenna when purchased. A kit will be available from service for owners requiring an external antenna for using the operator inside a garage with aluminum siding and a steel garage door. The receiver emissions per 15.109 limits were measured with both a wire antenna (Page 68) and per 15.111 using a 50 ohm termination at the antenna port (Page 69).

A set of plots follows with the information obtained from the conducted antenna test in accordance with 15.111 (Pages 70 – 80).

CONDUCTED EMISSIONS:

The last plots are the data from the conducted power line tests per 15.107 page 15-405. This test was performed using the quasi peak detector per 15.35(b) page 15-203, 15-407 page 15-405 (Plots Pages 81 – 84).

All tests were performed using ANSI C63.4 specifications.

Operator Radiated Emissions From Operator Electronics

Pre Scan Frequency Mhz	High Emmission Mhz	Measurement Span Mhz	Antenna Factor dB	Coax Factor dB	Amplifier Gain dB	Meter Reading dBm	Limit dBm	Delta Limit dBm
30-50	40	20	2.3	1.05	27.13	-68.5	-43.2	25.3

280-300	290	20	17.7	3.4	25.45	-78.2	-56.6	21.6
300-320	310	20	18.2	3.6	25.3	-77	-57.4	19.6
320-340	330	20	18.9	3.7	23.65	-80.7	-59.9	20.8

Measurements made to 1 GHz. Readings above 340 MHz were below equipment noise floor.

A reduced span was required for some measurements, for example in the FM broadcast band, to avoid ambient signals above the allowed level for the operator.

Measurements made with Quasi-Peak detector. Sweep time was 0.1 second X Span (in MHz).

Video Bandwidth = 1MHz

Resolution Bandwidth = 1 MHz

NOTES ON RADIATED AND CONDUCTED EMISSIONS

B8Q ACSR4

June. 11, 1999

- 1) The reported receiver radiated meter readings are peak for frequencies under 1Ghz. For frequencies above 1 Ghz average levels were obtained . The average levels were obtained using the average detector function on the spectrum analyzer. The averaging of each point depends upon the number of samples already taken and last average amplitude .

$$Y_n = \frac{n-1}{n} * Y(n-1) + \frac{1}{n} Y_n$$

where Y_n latest average amplitude value in display units

n current sample number

$Y(n-1)$ last average amplitude in trace memory

Y_n new amplitude entry from analyzer

The new amplitude value Y_n is weighted more heavily by the last average amplitude Y_{n-1} than the new amplitude entry, Y_n .

When n equals the limit set, the last average amplitude is gradually replaced with new data. Thus, the average will follow a slowly changing signal response, particularly if the sample limit is small.

- 2) The readings shown with an asterisk (*) represent the ambient noise floor. They are the lowest measurements possible with the equipment available at the given frequency. This level is below the allowed limit in each case.

- 3) The spectrum was scanned for radiated emissions from 1 MHz to 2 GHz.

- 4) Sample calculation: $\mu\text{V/m} = 10^{(107 + M + AF + CF - G)/20}$

$M = -28.0$

$AF = 2.0$

$\mu\text{V/m} = 631$

$CF = 2.0$

$G = 27.0$

- 5) AC Power-Conducted measurements were taken using the quasi-peak detector and the LISN.

- 6) A CW signal at 390 MHz was utilized to cohere the receiver during all testing.

7) All measurements were made using ANSI 63.4-1992.
